Introduction

For the development of intellectual and problem solving faced by students in their daily lives, critical thinking (C.T) skills are considered very important and also a part of life skills. In mathematics, Critical thinking skills are based on cognitive processes, which are used to solve different problems faced in daily life (Paul, 2007).

Critical thinking skills prepare students to learn about different sets and patterns of facts and figures and implementation of them to solve different problems in their routine lives. It motivates them to engage themselves in the world around themselves and to prepare others for thinking critically (Nelson, 2013).

Literature Review

Critical thinking skills are described the abilities of combining, mathematically reasoning, generalization, proving, rationalizing and evaluate systematically. An individual must have an attitude towards mathematics and intellectual constellation for the development and use of critical thinking in mathematics (Kereluik, 2013).

All over the world, mathematics is considered as fundamental and important subject for students to develop logical thinking and problem-solving skills. Mathematics education has a very vital role to educate students, how to think critically and solve the problems faced by them in their daily lives, acting as responsible and cooperative citizens in the society. Since last few decades, the objective of teaching mathematics is developing critical thinking and problem-solving skills among students (Kuntze et al., 2017).

According to the literature found related to the critical thinking in mathematics, it is a set of cognitive skills used to conclude logically and decision making in solving mathematical problems (Aizikovitsh-Udi & Cheng, 2015). It is also considered as an attitude to reflect regarding use and role of mathematics in different aspects of society i.e., social, political and cultural settings for the promotion of democracy in society. The first point described the significance of development of critical thinking among students to acquire different skills to solve problems and decision making in their daily lives. Whereas, second point highlights the importance of teaching of mathematics and development of critical thinking as reflection of analysis and evaluation of society. Furthermore, this described the importance of imparting critical thinking skills among students related to cognitive and social aspects of learning of mathematics as subject (Gutstein et al., 1997).

Material and Methods

Research Design

The main purpose of the study was to develop and validate critical thinking in mathematics test (CTMT) for 10th grade students. The study was developmental research. The study includes seven steps ranging from development to validation phase (content selection, table of Specification, development of the Items, validity, pilot testing, item Analysis and final instrument).

Results and Discussion

Development of Critical Thinking in Mathematics Test (CTMT)

The development and promotion in critical thinking is the foundation for academics. Bloom's Taxonomy used as base in teaching and learning for development of SLOs from curriculum. The taxonomy is very effective and mostly uses to assess different types of knowledge (factual, conceptual, procedural, and metacognitive) and development of higher-level cognitive skills (remembering, understanding, applying, analyzing, evaluating and creating). Bloom's Taxonomy is a perfect guide for an effective teacher (Heonga et al., 2012). Critical thinking of 10th grade students was tested through (MCQs). Final three levels of Blooms' Taxonomy (Analyzing, Evaluating and Creating) were taken as critical thinking.

Content for Critical Thinking in Mathematics Test (CTMT) in Mathematics

The content selected for the critical thinking MCQs test was a curriculum provided by Punjab Text Book Board (2006) Pakistan, titled as Text Book of Mathematics10th grade studied in all Punjab. This content is divided in 13 chapters, 50% of all syllabus (6 chapters) were selected. The content was consisted of 103 students learning outcomes having 34 SLOs related to upper three levels (analyzing, evaluating, and creating) of Bloom's taxonomy which were constructed by the help of (National Curriculum for Mathematics Grades IX – X, 2006)

Table of Specification for Critical Thinking in Mathematics Test (CTMT)

It is very difficult to decide how a researcher or teacher can measure critical thinking by a typical scoring scheme that supported by factual concepts. Scoring the level and quality of human thinking and reasoning is not a bed of roses. That's why researcher made MCQs test to Measure critical thinking. For the purpose teacher must use graded tests supported by a well-established scoring schemes or table of specification (Abdullaha & Osmanb, 2010).

Thus, the below-mentioned table of specification (TOS) was incorporated for the development of the test, namely Critical Thinking in Mathematics Test (CTMT).

Table 1
Table of Specification for Critical Thinking in Mathematics Test (CTMT)

Sr. No.	Chapter Name	, ,	Evaluating Questions	Creating Questions	Total	%Weightage
1	Theory Of Quadratic Equation	0	02	02	04	6
2	Partial Fraction	08	0	0	8	12

3	Sets And Functions	06	20	08	34	50
4	Basic Statistics	06	08	08	22	32
	Total	20	30	18	68	100

Table 1 shows the table of Specification CTMT. Two MCQs were developed against each SLO. There were 34 SLOs related to the analyzing, evaluating and creating levels of cognitive domain. This test consisted the domains of analyzing (20) and evaluating (30) and domain of creating (18).

Development of the Items of Critical Thinking in Mathematics Test (CTMT)

Primarily, sixty-eight (68) items (two-tiered Multiple-Choice Questions) and the answer key were developed for the Critical Thinking in Mathematics Test (CTMT) by the penal discussion of 5 subject specialists of Mathematics at QAED Pasrur, District Sialkot and QAED Narowal. The items and the answer key of the preliminary draft were discussed with the experts for guidance, restructuring, and rectification. Expert opinion was got from the items' developers, items reviewers and experts of Punjab Examination Commission Lahore. All the experts provided their valuable opinion about the instruction, diagrams, construct, relevancy, appropriateness, and level of the stem's cognitive domain and the distractors, language clarity, meaningfulness of the items, and content coverage.

Validity of Critical Thinking in Mathematics Test (CTMT)

Without ensuring the validity, a test gain nothing. Face validity refers to the relevance, clarity, reasonableness, and unambiguousness of the items (Oluwatayo & Adebule, 2012). Content validity is essential in the achievement test. It refers to the extent to which a test measures a representative sample of the subject matter content. Principally, Construct Validity deals with the psychological meaningfulness of the test. Taherdoost (2016), cited that it discriminates one latent variable with other latent variables (i.e., how "a" discriminates with b, c, and d). Criterion-related validity is the extent to which the test performance is related to some other valued performance measure (Aulia et al., 2017). The overall validity of tests is improved if items of the test are appropriately analyzed (Odukoya et al., 2018). Educational researchers have already specified various components and measuring techniques to ensure validity.

Therefore, construct validity was ensured by item analysis, and criterion predictive validity was ensured by discriminant analysis. Similarly, validity, including content validity and face validity, was ensured by allocating appropriate weightage/percentage to SLOs and content. Similarly, it was ensured after seeking the valuable opinion of Subject Matter Experts (SMEs). They provide their opinions

on each item of the test in terms of "Essential", "Necessary," and "Un-necessary" item. Therefore, the Content Validity Ratio (CVR) and Content Validity Index (CVI) was calculated accordingly.

Hence, 54 items were retained, and fourteen (14) items were deleted. Similarly, Content Validity Index (CVI) value was computed to ensure the validity of the test. Its value remained 0.92, which was greater than 0.7, which is an acceptable value. This indicates that experts endorsed the validity, including content validity and face validity.

Pilot Testing of Critical Thinking in Mathematics Test (CTMT)

The Critical Thinking in Mathematics Test (CTMT) comprising fifty-four (54) items was pilot tested on 280, 10th grade students. Different quality statistics like the level of difficulty (p), Discriminating Power (D), and Test Item Reliability (Aulia et al., 2017) of the Critical Thinking in Mathematics Test (CTMT) were computed by using M.S. Excel, 2013.

Level of difficulty (p)

Aulia et al. (2017), have described five levels of item difficulty based on Prop Correct value, i.e., very difficult, difficult, average, easy, and very easy. The items having proportion correct value ranging from 0.000 to 0.099 are termed as very difficult. The items are called "difficult" with proportion correct value ranging from 0.100 – 0.299, "average" with proportion correct value ranging from 0.701 – 0.900, and "very easy" with proportion correct value ranging from 0.901 – 1.000.

Discriminating Power (D)

Discriminating power (D) differentiates between the high achievers (upper quartile students who answered correctly) and low achievers (lower quartile students who responded correctly) (Aulia et al., 2017). It was identified that Discriminating Index is the primary method to measure discriminating power (D). Whereas, Zaidi et al. (2018), pointed out that a point-biserial correlation (rpbis) is used to measure discriminating power (D). The value of point biserial indicates that the right persons are receiving the correct item. It further indicates the predictive power of the item. According to Aulia et al. (2017), Discriminating power of items on point Biserial value is indicated as; equal or below 0.199 (Very Low) needs to drop out or complete revision, 0.200-0.299 (Low) needs revision, 0.300-0.399 (Average) declared as good and values range equal or above 4.00 (High) is declared as very good.

Discrimination Index (DI)

The capability of an item to discriminate among high-performing and low-performing students is called a Discrimination Index (Aulia et al., 2017). Its value ranges from -1 to +1. Kolte (2015), suggested the comprehensive criteria for Discrimination Index (DI) as; Range value of discrimination index below zero (Very poor) must be dropped, range value equal to zero (Poor) must be dropped, 0.00-0.19 (Acceptable) may be retained, 0.20-0.34 (Good) must be retained and range value equal or above 0.35 (Excellent) must be retained.

Reliability (a)

The alpha value indicates the test reliability in terms of low, average, and high reliable tests. A test with high reliability is one that reproduces the same relative importance of test scores for a group of students under different conditions or situations (Aulia et al., 2017).

The test is low/not sufficient reliable if the alpha value ranges from 0.000 to 0.400. Similarly, it is average/sufficient reliable if the alpha value ranges from 0.401 to 0.700. However, the test is good/high reliable if the alpha value ranges from 0.701 to 1.000.

Item Analysis of Critical Thinking in Mathematics Test (CTMT)

Different values like Point Biserial, Discriminating Index and difficulty level were computed by using M.S Excel 2013 software.

Table-2 represents the item-wise statistics of the Critical Thinking in Mathematics Test (CTMT). Descriptive statistics results of the test provide necessary information regarding the pilot testing. Twenty-four (24) items of the Critical Thinking in Mathematics Test (CTMT) remained below the acceptable value of quality items.

Final Critical Thinking in Mathematics Test (CTMT)

By adopting the above-cited, evidence-based review of test items, poorperforming items were dropped out from the test. Only thirty (30) Multiple Choice Questions (MCQs) remained fit to retain after item analysis. After removing the weak items, the reliability (Cronbach's alpha value) of the CTMT on valid items was 0.826, which is higher than 0.7. Thus, Critical Thinking in Mathematics Test (CTMT) was highly reliable. Test Statistics of the final Test (CTMT) in the below-mentioned table indicates item-wise test statistics consisting of thirty (30) Multiple Choice Questions (MCQs).

Table 3

Conclusions

- 1. Critical Thinking in Mathematics Test (CTMT) can actually measure critical thinking in mathematics of 10 grade students.
- 2. Content Validity Index (CVI) value remained 0.92, which was greater than 0.7, which is an acceptable value. Each item was found statistically significant.
- 3. The estimated difficulty level of items ranges from 0.300 0.700 which means there were no item that was too difficult or too easy.
- 4. Discrimination Index (DI) of items ranged from 0.20-0.34 (Good) and equal or above 0.35 (Excellent), which means all retained items were good and excellent.
- 5. The reliability (Cronbach's alpha value) of valid items was 0.826, which was higher than 0.7. Thus, Critical Thinking in Mathematics Test (CTMT) was highly reliable.
- 6. Final Critical Thinking in Mathematics Test (CTMT) consisted of 30 MCQs items (12 Analyzing MCQs, 10 Evaluating MCQs and 08 Creating MCQs).

Recommendations

- 1. On the basis of conclusions, it is recommended that Critical Thinking in Mathematics Test (CTMT) is valid and reliable. So, it may be used for formative and summative assessment.
- 2. Further tests to assess critical thinking of students in other science subjects may be developed.
- **3.** Teachers may be trained to develop different tests to assess critical thinking of students for better learning.
